

## Homework #3: Numerical Integration

- The simplest way to perform this integration is called the trapezoid method. One divides the  $x$  range into small segments  $\Delta x$  and assumes that for each  $\Delta x$

$$\int_x^{x+\Delta x} f(x)dx \approx \frac{(f(x+\Delta x) + f(x))\Delta x}{2} \quad (1)$$

$$\text{Area}(\text{trapezoid}) = 0.5 * (f(x+\Delta x) + f(x)) * \Delta x$$

The full integral is obtained by summing up all the areas of each  $\Delta x$ . Note, that the edge points have to be treated carefully.

- Write a program that calculates the following integral:

$$\int_{-2.5}^2 f(x)dx \quad (2)$$

where

$$f(x) = 10x^2 - x^3 \quad (3)$$

- Your program should compare the results of the numerical integration using the trapezoid method with the analytical results as obtained by calculating  $F = \int_{-2.5}^2 f(x)dx$ . The number of intervals must be large enough so that the results will fall within an accuracy of  $10^{-3}$  from each other.

- General guidelines for submitting C programs:**

The final program should contain a **reasonable** amount of **comment lines** which explain the program. Try to address the following points:

- Describe the main variables of the program.
- Explain your algorithm (briefly).
- Explain non-trivial C lines which might confuse the reader.

Good luck
